

IN THE ABSTRACT

Please replace the Abstract of the disclosure with the following:

The invention relates to a method of reconstructing the current flow, or the bolus arrival times, in a vessel system~~(6)~~. For the sections (i) of the vessel tree~~(6)~~, bolus arrival times (m_i) are measured, for example in connection with an injection of contrast medium. Based on this measured data, linear programming is then used to calculate model bolus arrival times (t_i), which, on the one hand, through minimization of the function $E = \sum |m_i - t_i|$, are as close as possible to the measured data, and, on the other, by adherence to the boundary condition $\Delta_i = t_i - t_{p(i)} \geq 0$, ensure the monotony of the propagation, wherein $p(i)$ is the index of the vessel section in front of vessel section (i). Preferably, as smooth as possible a progression is compelled by means of an additional minimization of $E_m = \sum |t_i''|$.
